

subprocess

Yves Guidet

V 2.5.4 (May 15, 2018)

Un script :

```
1 #! /usr/bin/env python2
2 # -*- coding: utf-8 -*-
3
4 #     la date via commands
5
6 k = 'date'
7
8 import commands
9 d = '     date = '
10 d += "'"
11 d += commands.getoutput(k)
12 d += "'"
13
14 print d
```

Aïe :

```
yves@bella:Py3k$ python3
Python 3.5.2 (default, Nov 23 2017, 16:37:01)
[GCC 5.4.0 20160609] on linux
Type "help", "copyright", "credits" or "license" for more info
>>> import commands
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ImportError: No module named 'commands'
```

Fonctionne très bien, et substitue *subprocess* à *commands*.
